1. Role in the project

In the PIXIU FLOW project, my role was mainly related to product planning, product structure, business logic, documentation, and product testing. I was not only involved in listing ideas, but also in turning the original website concept into a clearer product structure that the team could use for design, coding, report writing, and final demonstration.

At the beginning of the project, I contributed to developing the main idea of PIXIU FLOW. The website was created as a financial management platform for micro and small businesses, especially business owners who may not have strong accounting or financial knowledge. The problem we wanted to solve was that many small business owners still manage their sales, expenses, inventory, and profit manually. They may write information in notebooks, use simple spreadsheets, keep paper receipts, or remember transactions by memory. Because of this, they may not know their actual profit, cash situation, product performance, or stock condition clearly.

Based on that problem, I helped define what PIXIU FLOW should do as a product. The website should allow users to record revenue, record costs, manage products, track inventory, review transaction history, and view financial indicators on a dashboard. My role was to help connect these business needs with the actual website structure. This means I worked on identifying what information users need to input, how the system should process that information, and what outputs should be shown to users.

One of my main responsibilities was working on the inventory sitemap. I helped design the sitemap for the inventory section to clarify what pages and functions should be included. The purpose of this sitemap was to identify the necessary input and output for inventory management. For example, the system needs input such as product name, product category, cost price, selling price, stock quantity, supplier, stock-in date, and low-stock threshold. From these inputs, the system can produce outputs such as current stock quantity, inventory value, low-stock alerts, product list, and inventory summary. I also contributed to the mid-term report of the project. My work included writing and organizing important sections such as the project logic chain, input-financial logic-output table, and minimum viable version. These sections were important because they explained the foundation of the product before the team moved further into design and coding. They clarified the business problem, target users, user tasks, system inputs, financial formulas, expected outputs, and MVP scope.

In the later stage of the project, I participated in demo testing and error checking. I ran through the product flow, checked whether the prototype followed the planned user flow, reviewed whether the logic was understandable, and identified parts that needed correction. I also helped write the final explanation of the website input, user flow, and processing logic so that the product could be explained clearly in the final report and presentation.

Overall, my role was to make sure that PIXIU FLOW had a clear product direction, a logical system structure, and a practical connection between financial concepts and website features.

2. Personal Footprint

My personal footprint in PIXIU FLOW can be seen most clearly in the product planning, inventory structure, financial logic, and documentation of the website. The first clear footprint is the website idea and product direction. I helped the team shape PIXIU FLOW as a simple financial management tool for micro and small businesses. Instead of building a complex accounting or ERP system, the idea was to create a website that focuses on the most important daily business activities: recording sales, recording costs, checking inventory, and understanding profit and cash flow. This direction helped the team keep the product realistic within the course timeline while still solving a real business problem.

The second footprint is the inventory sitemap. Inventory is one of the most important parts of PIXIU FLOW because product-based businesses need to know what they have in stock, how much each product costs, how much it sells for, and when they need to restock. I helped design the inventory sitemap to organize the inventory function into a clear structure. This sitemap showed what information should be entered, what pages were needed, what output should be displayed, and how inventory should connect with other parts of the system.

For example, when a user adds a product, the product information should not only appear in the product list. It should also support transaction recording because the user can later select that product when recording revenue or purchase costs. When a user sells a product, the stock quantity should decrease. When a user records an inventory purchase, the stock quantity should increase. This shows that inventory is not a separate feature; it is connected to revenue, cost, dashboard reports, and transaction history.

The third footprint is the logic documentation. I helped explain how PIXIU FLOW processes user data and converts it into useful business indicators. This includes the logic for revenue, cost, gross profit, net profit, cash flow, inventory value, stock quantity, and low-stock warnings. I also helped clarify the difference between profit and cash flow, which was an important correction during the writing process.

Profit focuses on the relationship between revenue and the costs related to selling products. Cash flow focuses on the money coming in compared with the money paid out for inventory purchases or other expenses. In PIXIU FLOW, cash paid refers to money paid for purchasing goods or paying other costs. This distinction matters because a business can look profitable but still have cash flow problems if it spends too much money on inventory or expenses.

The fourth footprint is the input, user flow, and logic explanation that I wrote for the final website. These sections explain how users interact with the system from the moment they register until they review financial reports. They also explain what data the system collects and how it processes that data. This helped make the final product easier to understand for both the team and the audience.

The final footprint is demo testing. By testing the product and checking for errors, I helped make sure that the prototype was not only visually complete but also logically consistent. I reviewed whether the screens matched the planned flow, whether the input fields were suitable, and whether the dashboard indicators made sense from a business perspective.

3. Tasks

During the project, I completed several specific tasks.

First, I helped create the original product idea for PIXIU FLOW. I joined the discussion about the problem faced by micro and small business owners and helped define the website as a financial tracking platform. The product idea focused on helping users manage revenue, expenses, inventory, profit, and cash flow without needing advanced accounting knowledge.

Second, I worked on the inventory sitemap. I designed the structure of the inventory section and identified the information needed for inventory management. This included product data, category data, supplier data, stock quantity, stock-in information, cost price, selling price, and warning level. I also considered what output users should receive from the inventory module, such as total stock quantity, inventory value, product list, low-stock warning, and product detail summary.

Third, I helped define the input-output structure of the website. I identified the main inputs needed in different parts of the system, including account information, business profile information, product information, revenue transactions, cost transactions, payment method, transaction date, and filters. I also helped define the outputs that the system should display, including revenue, cost, profit, cash flow, inventory quantity, inventory value, transaction history, dashboard cards, and charts.

Fourth, I contributed to the mid-term report. I worked on the sections related to the project logic chain, input-financial logic-output table, and minimum viable version. These sections helped explain the logic of the product in a formal report format. They also helped the team show that the project had a clear problem, target user, financial logic, and feasible MVP scope.

Fifth, I helped write the final input section of the website explanation. This section described what information PIXIU FLOW receives from users. It included account setup information, business profile data, revenue transaction input, cost transaction input, product and inventory data, and search or filter input.

Sixth, I wrote the final user flow section. This section described how users move through PIXIU FLOW step by step. I explained flows such as registration, login, business setup, product setup, recording revenue, recording costs, entering multiple transactions, viewing the dashboard, checking transaction history, and monitoring inventory. I made the flow more specific so that it did not only say “the user enters information,” but clearly explained what happens at each stage.

Seventh, I wrote the processing logic section. This section explained how PIXIU FLOW calculates and updates financial and inventory data. I included logic for revenue calculation, cost calculation, gross profit, net profit, cash flow, payment status, inventory quantity, inventory value, low-stock warning, dashboard reporting, search filters, and transaction history updates.

Eighth, I reviewed and corrected the cash flow logic. At first, there was confusion between cost of goods sold and cash paid. I corrected the logic so that cash flow is explained as revenue compared with cash paid for inventory purchases or other business expenses. This made the explanation more consistent with how the website actually works.

Ninth, I participated in demo testing and software checking. I tested the website flow by moving through the prototype screens and checking whether each function was understandable. I reviewed the dashboard, transaction pages, transaction history, product and inventory pages, and input forms. I checked whether the website matched the planned logic and whether there were any confusing or inconsistent parts.

Finally, I helped prepare the product explanation for the final report and demo. This included explaining the connection between the website screens, the logic behind them, and the final business value for users.

4. File, Feature, Data, Logic, Interface, Document, or Demo Contributed

1. Website Idea and Product Direction

I contributed to the early product idea of PIXIU FLOW. The website was designed as a profit tracking and financial management platform for micro and small businesses. My contribution helped define the main direction of the product: simple financial tracking, practical inventory management, and easy-to-understand dashboard reporting.

This contribution was important because the team needed a clear product direction before designing screens or writing code. Without a clear idea, the website could become too broad or unrealistic. By focusing on small business finance and inventory tracking, the project became more specific and feasible.

2. Inventory Sitemap

I contributed to the inventory sitemap using diagrams.net. This sitemap helped define the structure of the inventory module and how it connects with the rest of the website.

The sitemap helped answer several important questions:

- What pages should the inventory section include?
- What input fields are needed for inventory?
- What output should users see?
- How does inventory connect with revenue transactions?
- How does inventory connect with cost or purchase transactions?
- How should stock quantity be updated?
- What information should appear on the inventory dashboard?

The sitemap became a planning tool for later design, coding, and testing activities.

3. Mid-term Report

I contributed to the mid-term report, especially the planning and logic sections. The report explained the project's progress and showed that the team had already developed the product logic, input-output structure, MVP scope, sitemap, and prototype direction.

The parts I contributed to include:

- A. Project Logic Chain.
- B. Input, Financial Logic, and Output Table.
- C. Minimum Viable Version.

These sections helped explain the project in an organized way. The project logic chain described the business problem, target users, user tasks, difficulties, technology support, input, logic, output, and user actions. The input-financial logic-output table explained how each input connects to financial meaning, calculation rules, and final output. The MVP section clarified which features should be included in the minimum version and which advanced features should be left out.

4. Input Documentation

I wrote the input documentation for PIXIU FLOW. This part explained what information the system receives from users.

The input documentation included:

- Account information, such as email, phone number, owner name, password, and password confirmation.
- Business profile information, such as business name, business type, main currency, and country.
- Product information, such as product name, category, unit, cost price, selling price, and stock alert threshold.
- Inventory information, such as opening stock, stock-in quantity, supplier, purchase date, and notes.
- Revenue transaction information, such as customer, product, selling price, quantity, date, and payment method.
- Cost transaction information, such as supplier, purchase cost, quantity, expense type, payment method, and due date.
- Filter and search information, such as date range, transaction type, product name, customer, supplier, and payment status.

This documentation made the website requirements clearer. It helped the team understand what data should be collected before the system can calculate reports or update inventory.

5. User Flow Documentation

I wrote the user flow documentation to explain how users move through the website.

The user flow covered:

- Registration and initial setup.
- Login.
- Business profile setup.
- Product and inventory setup.
- Recording revenue.
- Recording costs.
- Entering multiple transactions.
- Viewing the dashboard and reports.
- Checking transaction history.
- Searching and monitoring inventory.

I tried to make this section specific and practical. For example, instead of only saying that the user records a transaction, I described what information is entered, what the system checks, what calculation happens, and what data is updated after saving.

This user flow helps designers understand what screens are needed and helps coders understand how the system should behave after each user action.

6. Logic and Processing Rules

I wrote the logic and processing rules for the website. This was one of the most important parts of my contribution because PIXIU FLOW is a financial management website, so the logic must be clear and accurate.

The logic I wrote included:

- Account and business setup logic.
- Product and inventory processing logic.
- Revenue transaction logic.
- Cost transaction logic.
- Profit calculation logic.
- Cash flow logic.
- Payment status logic.
- Dashboard and reporting logic.
- Transaction history logic.
- Multiple transaction entry logic.
- Search and filter logic.
- Overall system logic.

This section explained how PIXIU FLOW converts user input into useful output. For example, when a user records a revenue transaction, the system calculates revenue, updates transaction history, reduces stock quantity, and refreshes dashboard results. When a user records an inventory purchase, the system increases stock quantity, records cash paid, updates inventory value, and stores the transaction.

7. Demo Testing and Error Checking

I also contributed to product testing and demo preparation. I tested the website prototype by going through the main user flows and checking whether the system worked logically.

During testing, I reviewed:

- Whether users could register and set up business information logically.
- Whether product and inventory input fields were clear.
- Whether revenue and cost transaction forms included enough information.
- Whether dashboard indicators were understandable.
- Whether transaction history displayed useful information.
- Whether inventory figures connected with product and transaction data.
- Whether the financial logic matched the intended website function.
- Whether any wording, flow, or layout could confuse users.

This testing helped make the product more ready for demo because the final presentation needs to show not only the interface but also how the system works.

5. How My Contribution Connects to the Final Product

My contribution connects to the final product in several important ways.

First, the website idea and product planning helped define the purpose of PIXIU FLOW. The final product is not just a random collection of pages. It is built around a clear business problem: helping small business owners understand revenue, costs, inventory, profit, and cash flow more easily. My contribution helped shape this problem into a website concept that could be developed within the course.

Second, the inventory sitemap directly connects to the final inventory function. The inventory page in the final product includes product information, stock quantity, inventory value, categories, suppliers, and warning indicators. These elements are linked to the planning work done through the sitemap. The sitemap helped the team understand what the inventory module should contain and how it should interact with other functions.

Third, the input documentation connects to the final product because every form in the website depends on clearly defined input fields. For example, the revenue form needs product name, selling price, quantity, customer, date, and payment method. The cost form needs cost type, supplier, product or expense details, amount, payment method, and date. The product page needs product name, category, unit, cost price, selling price, stock quantity, and alert threshold. By defining these inputs, I helped make the website forms completer and more purposeful.

Fourth, the user flow documentation connects to the final product because it describes how users should actually use the website. It makes sure that the product is not only designed page by page but also works as a complete process. Users can register, set up a business profile, add products, record transactions, check reports, and review inventory. These flows make the product easier to test and explain.

Fifth, the logic documentation connects directly to the dashboard and reporting functions. The dashboard depends on calculations such as revenue, cost, profit, cash flow, and inventory value. If these formulas are unclear, the dashboard cannot be explained properly. My contribution helped clarify how the numbers should be calculated and what they mean for users.

Sixth, demo testing helped connect the planned product with the actual prototype. During testing, I checked whether the screens matched the expected logic and whether users could understand the system. This helped identify gaps between the written plan and the actual product. As a result, my work helped make the final product more consistent, understandable, and ready for demonstration.

Overall, my contribution acted as a bridge between the business idea, the website structure, the written report, the system logic, and the final demo.

6. Evidence of Contribution

7. Lesson learned from the project

Through this project, I learned how to move from a broad business idea to a structured digital product. At first, the problem of helping small businesses manage finance seemed very large. It included revenue, expenses, products, suppliers, stock, profit, reports, and cash flow. By working on the sitemap and documentation, I learned how to break this broad problem into smaller functions that can be designed and tested.

I also learned that product planning is very important before coding. If the team starts designing or coding too early without a clear sitemap or input-output structure, the product can become inconsistent. A clear plan helps everyone understand what pages are needed, what each page should do, and how different features connect with each other.

Another important lesson was the difference between accounting logic and cash flow logic. During the project, I realized that financial terms must be used carefully. Revenue, cost, profit, cash paid, and cash flow are related, but they do not mean the same thing. For example, cost of goods sold is used to calculate profit, while cash paid represents money that goes out of the business for inventory purchases or other expenses. Understanding this difference helped me write a more accurate explanation for the website.

I also learned more about inventory management. Inventory is not just a list of products. It is connected to purchasing, selling, cost calculation, stock movement, supplier management, and business decisions. If inventory is not managed properly, a business may buy too much stock, run out of important products, or keep slow-moving inventory for too long.

In addition, I learned that user flow affects how useful a product is. Even if the system has good features, users may not benefit from them if the flow is confusing. Since PIXIU FLOW targets small business owners who may not be familiar with financial tools, the user flow must be simple and direct. This helped me think more from the user's perspective rather than only from the system's perspective.

I also learned that documentation is an important part of teamwork. The mid-term report, sitemap, input table, logic explanation, and user flow were not just documents for submission. They helped the team communicate and make decisions. Designers could use them to design screens, coders could use them to understand the system logic, and presenters could use them to explain the product.

Finally, through demo testing, I learned that a product should be checked not only for appearance but also for logic. A page may look finished, but it still needs to be tested to see whether the data flow, calculations, and user actions make sense.

8. Difficulties and How I Handled Them

One difficulty I faced was deciding the correct scope of the website. PIXIU FLOW could include many advanced features, such as AI pricing recommendations, competitor benchmarking, dynamic pricing, profit simulation, full accounting records, and advanced reports. However, the course timeline was limited, so we had to decide what should be included in the MVP and what should be left out. I handled this by focusing on the core workflow: business setup, product setup, revenue recording, cost recording, inventory tracking, dashboard reporting, and transaction history.

Another difficulty was designing the inventory sitemap. Inventory connects to many other features, so it was not easy to decide where each function should belong. For example, product creation connects with inventory, but it also connects with revenue recording because products are selected when users record sales. Inventory purchases connect with cost recording, but they also update stock quantity. I handled this by separating the inventory system into input, process, and output. This made the structure easier to organize.

A third difficulty was writing the financial logic clearly. Financial logic can become confusing if formulas are written without explanation. For example, users may not immediately understand the difference between gross profit and net profit, or between cash flow and profit. I handled this by writing the logic in simple business language and using examples with numbers. This made the explanation easier to understand.

A fourth difficulty was correcting the cash flow logic. At one point, there was a risk of mixing up cash paid with cost of goods sold. This would make the explanation inaccurate because cost of goods sold relates to products sold, while cash paid relates to money actually paid for purchases or expenses. I handled this by reviewing the actual product design and rewriting the cash flow logic so that it matched the system correctly.

A fifth difficulty was making the user flow specific without making it too repetitive. The first version of the user flow repeated similar words and did not describe each step deeply enough. I improved it by rewriting the flows based on actual screens and actions. I described what the user enters, what button is clicked, what the system checks, and what data is updated after each step.

Another difficulty appeared during demo testing. Some screens looked visually complete, but I still needed to check whether they matched the original sitemap and logic. I handled this by comparing the prototype with the planned input, user flow, and processing rules. This helped identify whether the product was consistent from planning to final demo.

9. Message to Future Students

My message to future students is to start with the product logic before focusing too much on the interface. A good design is important, but the website must first have a clear purpose, clear input, clear processing rules, and clear output. If the logic is unclear, the product may look good but become difficult to explain or use.

For a project like PIXIU FLOW, it is useful to prepare a sitemap early. The sitemap helps the team see the whole product structure before building individual pages. It also helps avoid missing important features or creating pages that do not connect well with each other.

Future students should also define the MVP carefully. It is better to build a smaller product that works clearly than to include too many advanced features that cannot be completed properly. Advanced features can be placed in the future development scope, while the MVP should focus on the core problem.

Another piece of advice is to test the product from the user's perspective. Do not only ask whether a button works. Ask whether the user understands what to do, whether the input fields are clear, whether the output is useful, and whether the result helps users make better decisions.

Finally, students should keep evidence of their work from the beginning. Save sitemap links, report drafts, screenshots, group notes, testing comments, and prototype images. These materials are useful for proving individual contribution and explaining personal learning at the end of the project.
